### *How forecasts are made*

Most of the annual streamflow in the western United States originates as snowfall that has accumulated in the mountains during the winter and early spring. As the snowpack accumulates, hydrologists estimate the runoff that will occur when it melts. Measurements of snow water equivalent at selected manual snow courses and automated SNOTEL sites, along with precipitation, antecedent streamflow, and indices of the El Niño / Southern Oscillation are used in computerized statistical and simulation models to prepare runoff forecasts. These forecasts are coordinated between hydrologists in the Natural Resources Conservation Service and the National Weather Service. Unless otherwise specified, all forecasts are for flows that would occur naturally without any upstream influences.

Forecasts of any kind, of course, are not perfect. Streamflow forecast uncertainty arises from three primary sources: (1) uncertain knowledge of future weather conditions, (2) uncertainty in the forecasting procedure, and (3) errors in the data. The forecast, therefore, must be interpreted not as a single value but rather as a range of values with specific probabilities of occurrence. The middle of the range is expressed by the 50% exceedance probability forecast, for which there is a 50% chance that the actual flow will be above, and a 50% chance that the actual flow will be below, this value. To describe the expected range around this 50% value, four other forecasts are provided, two smaller values (90% and 70% exceedance probability) and two larger values (30%, and 10% exceedance probability). For example, there is a 90% chance that the actual flow will be more than the 90% exceedance probability forecast. The others can be interpreted similarly.

The wider the spread among these values, the more uncertain the forecast. As the season progresses, forecasts become more accurate, primarily because a greater portion of the future weather conditions become known; this is reflected by a narrowing of the range around the 50% exceedance probability forecast. Users should take this uncertainty into consideration when making operational decisions by selecting forecasts corresponding to the level of risk they are willing to assume about the amount of water to be expected. If users anticipate receiving a lesser supply of water, or if they wish to increase their chances of having an adequate supply of water for their operations, they may want to base their decisions on the 90% or 70% exceedance probability forecasts, or something in between. On the other hand, if users are concerned about receiving too much water (for example, threat of flooding), they may want to base their decisions on the 30% or 10% exceedance probability forecasts, or something in between. Regardless of the forecast value users choose for operations, they should be prepared to deal with either more or less water. (Users should remember that even if the 90% exceedance probability forecast is used, there is still a 10% chance of receiving less than this amount.) By using the exceedance probability information, users can easily determine the chances of receiving more or less water.

# **IDAHO WATER SUPPLY OUTLOOK REPORT**

**January 1, 2002**

## **SUMMARY**

Snowfall in the first half of winter was promising and delightful for winter recreation, but much more snow is still needed to provide adequate water supplies for irrigation, river runners, reservoir recreation, fish, hydropower and all those other users and uses. Currently, snowpacks range from 85-160% of average for most basins in Idaho, but this is only 35-65% of the April 1 seasonal peak. Combined storage for the state's 21 reservoirs and lakes is the 3<sup>rd</sup> lowest since 1958. The dry summer and fall have left a soil moisture deficit in parts of southern and eastern Idaho. Rivers remain low after last summer's near record low streamflow. Even with the current good snowpack on the ground that is starting to exceed last year's April 1 peak amounts, nobody can say the "Drought is over in Idaho." With more than half the winter still to come, the water supply picture can change for the better or worse. Keep those fingers crossed that the storms come back to Idaho like they did between Thanksgiving and Christmas and don't go to Buffalo, New York!

## **SNOWPACK**

The majority of Idaho's snowpacks range from 85% of average in the upper Snake basins to 160% in the basins south of the Snake River basins. The lowest snowpacks are 75% of average along the Idaho-Montana border in the Lochsa, Lemhi and Birch-Medicine Lodge basins. The highest snowpacks are in the lower elevations. Some of these sites are 200% of average and have even exceeded their seasonal average peaks. However, these are not the primary snow producing zones in Idaho. The higher elevation zones are, and this is where we need the snow to continue accumulating. With more than half the winter still to come, the water supply outlook could change for the better or worse. The amount of snow currently on the ground is only 35-65% of the normal seasonal peak that occurs around April 1. So we still have a way to go to reach these peaks by the end of the snow accumulation season. Let's keep our fingers crossed and hope the jet stream comes back across Idaho like it did between Thanksgiving and Christmas!

## **PRECIPITATION**

After a slow start, Mother Nature brought a series of storms between Thanksgiving and Christmas to jump-start the snow season in Idaho. December precipitation ranged from near normal in northern Idaho to almost twice normal across southern Idaho, especially in the low elevation snow zones. Fall rains and snow helped to recharge the soil moisture profile north of the Salmon River basin; however, the southern half of Idaho may still have a soil moisture deficit, especially where the first fall precipitation event fell as snow and remained on the ground. Water year to date precipitation is near normal in the Salmon, Wood and Lost, Upper Snake and Bear basins. Water year to date precipitation is 114-122% of average in the Panhandle, Clearwater, Weiser, Payette, Boise, and basins south of the Snake River.

## **RESERVOIRS**

Reservoir storage remains low throughout Idaho. Priest Lake, Dworshak, Lucky Peak and Brownlee reservoirs are reporting average storage for December 31. The southern Idaho reservoirs of Salmon Falls and Oakley are nearly empty. Salmon Falls Reservoir is the lowest in the state at 5% of capacity, 19% of average--the lowest December 31 storage reading since 1962. Oakley Reservoir is 13% full, 38% of average; Owyhee Reservoir is 15% full, 26% of average. The 8 major reservoirs in the upper Snake are one-third full or half of normal. Jackson Lake is 16% full, and Palisades Reservoir is only 31% full. The Payette reservoir system is 44% full, 70% of average; the Boise system is 34% full, 62% of average. The December 31 combined storage for 21 Idaho reservoirs and lakes is the 3<sup>rd</sup> lowest since 1958. The lowest years were December 31, 1992, and 1994 which also followed severe drought years.

Note: NRCS reports reservoir information in terms of usable volumes, which includes both active, inactive and in some cases dead storage. Other operators may report reservoir contents in different terms. For additional information, see the reservoir definitions in this report.

## STREAMFLOW

Streamflows remain low in Idaho, but that is normal for this time of year. Observed runoff for the April-July runoff season last year was low as predicted and ranged from 30-60% of average. With dry antecedent soil moisture and residual effects of the past drought years, water users should look at all five Exceedance Probability forecasts published this year to base their water management decisions. The "Interpreting Streamflow Forecasts" in the printed version further explains use of these Exceedance Forecasts. The Most Probable Streamflow Forecasts in Idaho range from 70-110% of average. The lowest forecasts are in the mainstem Snake River - American Falls inflow, Blackfoot Reservoir inflow, Snake River at King Hill and near Murphy at about 70% of average. The highest forecast is for Owyhee Reservoir inflow at 110% of average.

## RECREATION

Abundant snowfall after Thanksgiving jump started Idaho's winter recreation season. Cold temperatures have kept the snow light, dry and consistent with few noticeable layers. As a result, snow depths are above average for this time of year making conditions great for skiers and snowmobilers. Much more snow is needed in the high country to ensure a good boating season. For those river runners looking to select the best dates for floating the Salmon basin the potential range is wide open. A quick analysis of other years with a snowpack in the 90-110% of average range on January 1, resulted in the April-July Salmon River at White Bird ranging from 46% of average in 1992 to 130% in 1976.

## WHAT'S NEW?!

### New Streamflow Forecasts:

Streamflow forecasts were requested and developed for the Selway River near Lowell and Lochsa River near Lowell. These forecasts will help determine the water supply in the headwaters of the Clearwater River and provide specific forecasts for river runners.

### New 30 Year Average:

Averages used for comparison purposes were updated from the 1961-1990 period to the 1971-2000 period. The new averages are reflected in this publication. Old averages are being used for a few stations, which were discontinued, or water year 2000 is not available yet. These will be updated as the analysis is completed. The 30-year average period is based on World Meteorological Organization standards that water forecast agencies have adapted. Averages are revised or updated every 10 years. The most recent 30-year period is used for comparison purposes because it represents the current climatological conditions. Daily SNOTEL averages were developed for snow water content values and precipitation. Monthly averages were developed for snow courses, end of month reservoir storage and streamflow and are available on our Web page at: <http://idsnow.id.nrcs.usda.gov/>

**IDAHO SURFACE WATER SUPPLY INDEX (SWSI) As of January 1, 2002**

The Surface Water Supply Index (SWSI) is a predictive indicator of surface water availability within a watershed for the spring and summer water use season. The index is calculated by combining pre-runoff reservoir storage (carryover) with forecasts of spring and summer streamflow. SWSI values are scaled from +4.1 (abundant supply) to -4.1 (extremely dry), with a value of zero indicating a median water supply as compared to historical occurrences.

SWSI values are published January through May and provide a more comprehensive outlook of water availability than either streamflow forecasts or reservoir storage figures alone. The SWSI index allows comparison of water availability between basins for drought or flood severity analysis. Threshold SWSI values have been established for most basins to indicate the potential for agricultural water shortages.

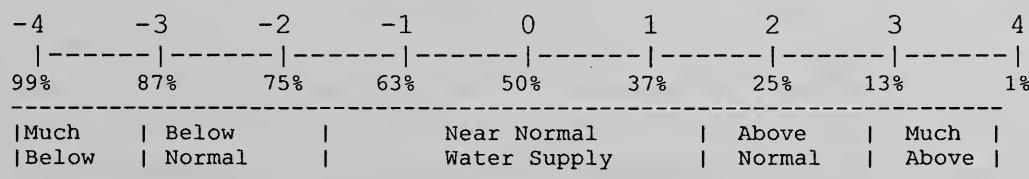

The following agencies and cooperators provide assistance in the preparation of the Surface Water Supply Index for Idaho:

US National Weather Service  
US Bureau of Reclamation  
Idaho Water Users Association

US Army Corps of Engineers  
Idaho Dept. of Water Resources  
PacifiCorp

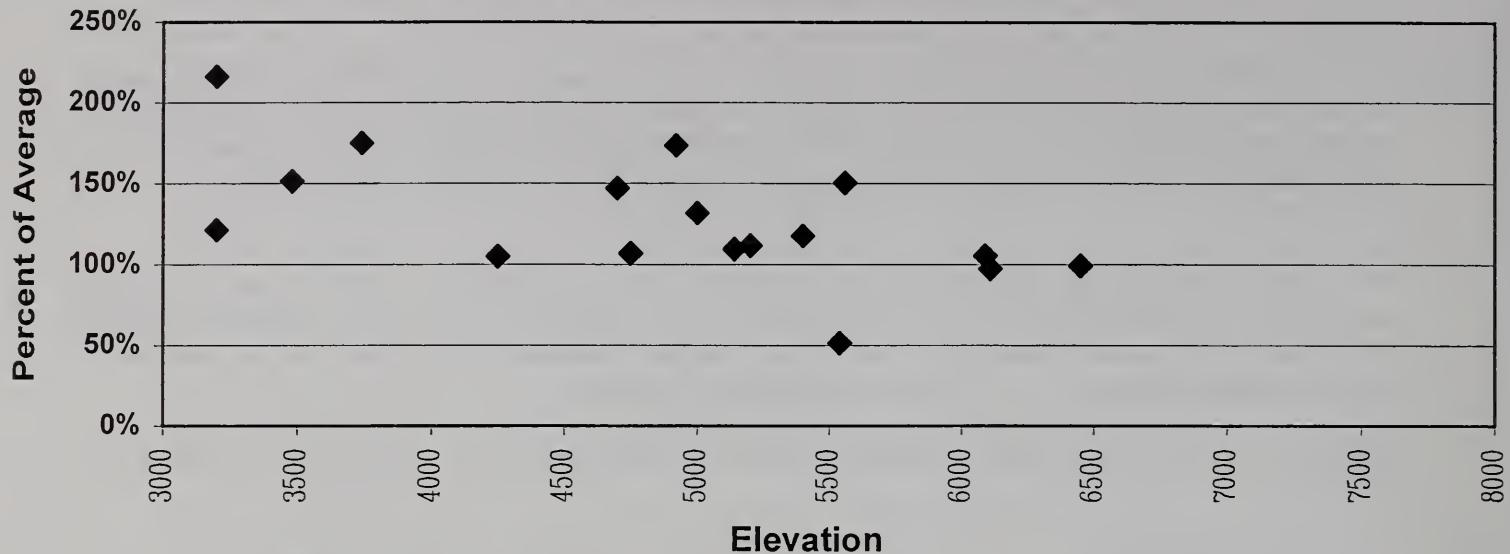

<i>BASIN or REGION</i>	<i>SWSI Value</i>	<i>Most Recent Year With Similar SWSI Value</i>	<i>Agricultural Water Supply Shortage May Occur When SWSI is Less Than</i>
PANHANDLE	-0.2	1984	NA
CLEARWATER	0.8	1990	NA
SALMON	0.2	1980	NA
WEISER	0.7	1980	NA
PAYETTE	-0.1	1976	NA
BOISE	-0.1	2000	-2.6
BIG WOOD	-1.4	2000	-1.4
LITTLE WOOD	0.4	1996	-2.6
BIG LOST	-0.7	1993	-0.8
LITTLE LOST	0.0	1996	0.0
HENRYS FORK	-1.5	1979	-3.3
SNAKE (AMERICAN FALLS)	-1.9	1989	-2.0
OAKLEY	-0.4	1994	0.0
SALMON FALLS	-0.1	1989	0.0
BRUNEAU	1.0	1996	NA
OWYHEE			NA
BEAR RIVER	-2.9	1990	-3.8

**SWSI SCALE, PERCENT CHANCE OF EXCEEDANCE, AND INTERPRETATION**

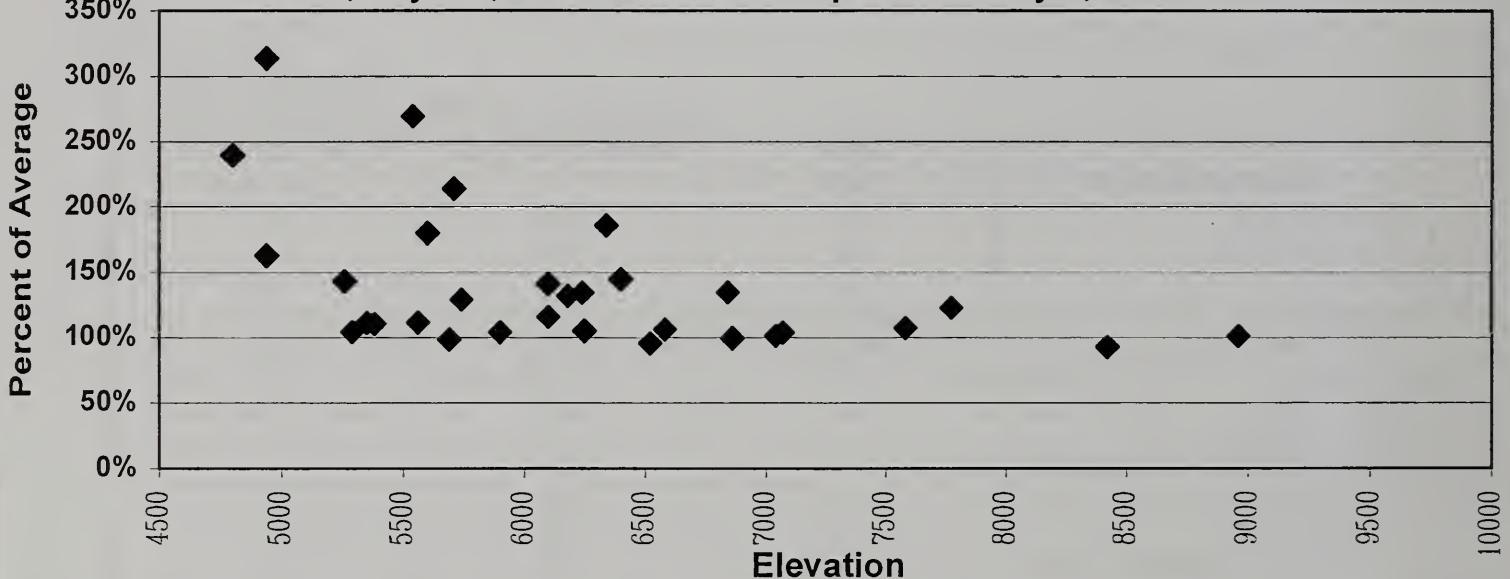

Note: The Percent Chance of Exceedance is an indicator of how often a range of SWSI values might be expected to occur. Each SWSI unit represents about 12% of the historical occurrences. As an example of interpreting the above scale, the SWSI can be expected to be greater than -3.0, 87% of the time and less than -3.0, 13% of the time. Half the time, the SWSI will be below and half the time above a value of zero. The interval between -1.5 and +1.5 described as "Near Normal Water Supply," represents three SWSI units and would be expected to occur about one-third (36%) of the time.

# PANHANDLE REGION

## JANUARY 1, 2002

## WATER SUPPLY OUTLOOK

The new water year started with October precipitation at 174% of average. November precipitation was 89% of average. December, one of the larger precipitation months, brought 116% of average precipitation. Water year to date precipitation is 117% of average, more than twice the amount that fell by this time last year. The snowpack ranges from 86% of average in the Pend Oreille basin to 129% in the Priest River basin. Bear Mountain SNOTEL site is currently at 30.6 inches of snow water and is about to exceed last year's peak of 31.2 inches of snow water that occurred on May 2! This is great news, but with more than half the winter still to come, snowpacks need to continue to build in the higher elevations. Priest Lake is storing near normal levels while Pend Oreille and Coeur d'Alene Lake are at 81% and 59% of average, respectively. Streamflow forecasts call for a range from 85-105% of average for these northern Idaho streams.

\* 90%, 70%, 30%, and 10% chances of exceeding are the probabilities that the actual flow will exceed the volumes in the table.

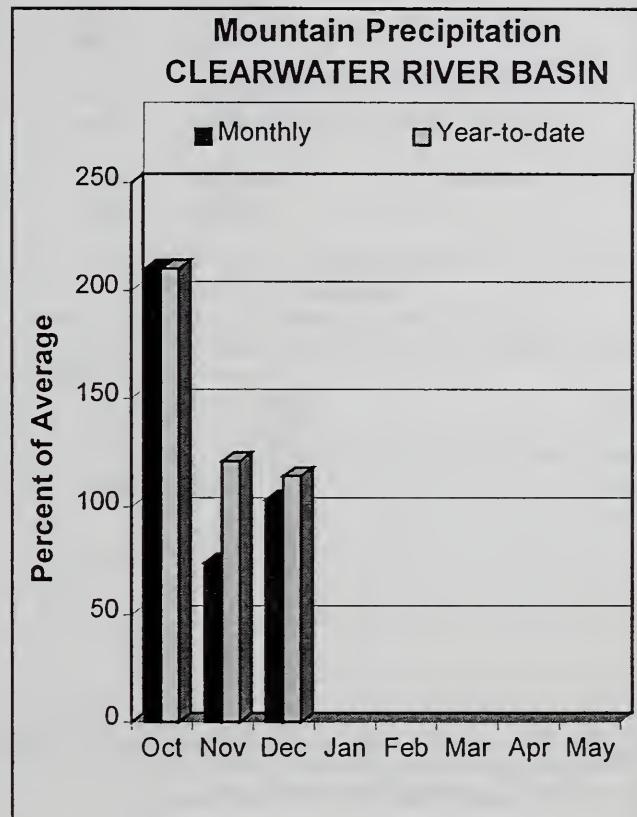

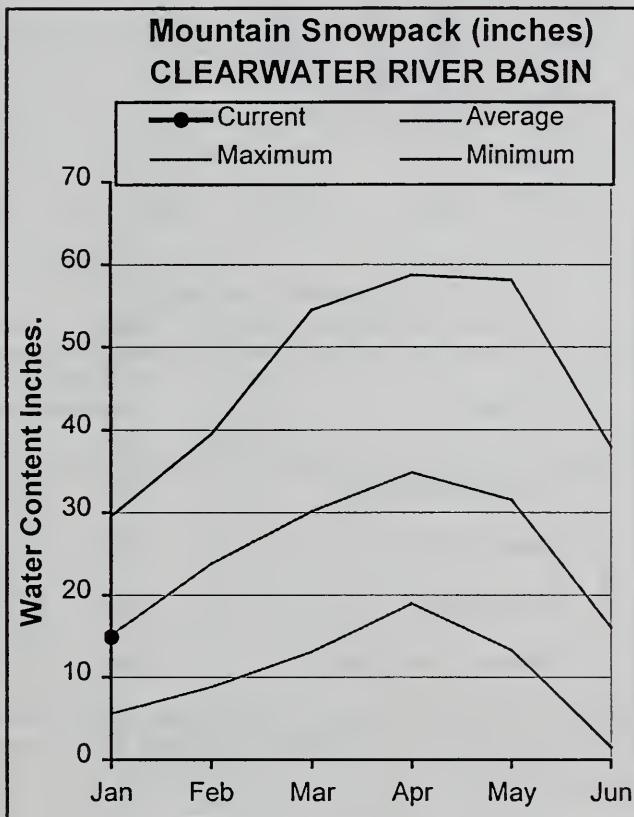

The average is computed for the 1971-2000 base period.

(1) - The values listed under the 10% and 90% Chance of Exceeding are actually 5% and 95% exceedance levels.

(2) - The value is natural flow - actual flow may be affected by upstream water management.

# CLEARWATER RIVER BASIN

## JANUARY 1, 2002

## WATER SUPPLY OUTLOOK

The new water year started on the right note with most SNOTEL sites receiving 10-20 inches for the October-November period. For many stations in the Clearwater River basin, this was the most recorded in October since daily SNOTEL precipitation records started nearly 20 years ago. December brought near normal precipitation amounts. Water year to date precipitation amounts remain above normal at 114% of average. Fall rains helped to recharge the soil moisture. As a result, this is one area of the state that may have a minimal soil moisture deficit, if any. Snowpacks range from a low of 75% of average in the Lochsa River to normal on the North Fork Clearwater River basin. Overall the Clearwater basin is 97% of average. Dworshak Reservoir is 66% of capacity, 103% of average. Just a reminder: NRCS includes the 1,452,000 acre-feet of inactive storage in our storage totals. The inactive storage accounts for 41% of the total capacity of the reservoir. Streamflow forecasts call for near normal runoff for this season. With more than half the winter still to come, normal or above normal precipitation is needed for the remaining winter months.

# SALMON RIVER BASIN

## JANUARY 1, 2002

## WATER SUPPLY OUTLOOK

December precipitation was 109% of average. Precipitation for the water year is normal. Snowpack percentages range from 78% of average for the Lemhi River basin, one of the lowest percentages in the state, to 115% for the Little Salmon River basin, twice the amount from a year ago. The snowpack on the Middle Fork Salmon River basin is 93% of average. Overall, the Salmon River basin is 94% of average. Streamflow forecasts call for 100% of average for the Salmon River at Salmon and 98% for the Salmon River at White Bird. A quick analysis of previous years with a snowpack in the 90-110% of average range on January 1, resulted in the April-July volume for the Salmon River at White Bird ranging from 46% of average in 1992 to 130% in 1976. River runners and water users of all types should hope for above normal precipitation for the remaining winter months to ensure a good water year.

# WEISER, PAYETTE, BOISE RIVER BASINS JANUARY 1, 2002

## WATER SUPPLY OUTLOOK

December precipitation varied across these west-central basins with low elevation SNOTEL sites such as Prairie and Camas Creek Divide receiving 170% of average. Higher elevation SNOTEL sites such as Deadwood Summit and Vienna Mine only received about 118% of average. Water year to date precipitation stands at 117% of average. The snowpack around 5,000 feet in elevation is nearly twice normal and has exceeded its seasonal average peak in some areas. This is good news, but the high elevation is much more critical in providing the snowmelt and runoff that feed the streams and fill our reservoirs. Some higher elevation SNOTEL sites are starting to exceed their peaks from last year. For example, Deadwood Summit SNOTEL site has 18.4 inches of snow water, which is normal for January 1 and twice the amount from a year ago. Deadwood Summit peaked on April 23, 2001, at 19.3 inches of snow water. The normal seasonal peak for Deadwood Summit is 48.2 inches of snow water on April 16, so we still have a long ways to get there. As a result of this precipitation pattern, snowpack percentages are the greatest in the low elevation drainages of Mores Creek at 164% of average and Mann Creek and Weiser basins at 130%. The Middle and North Fork Boise basins snowpack is the lowest at 110% of average. The Payette reservoir system is 44% full, 70% of average; the Boise system is 34% full, 62% of average. Streamflow forecasts call for near normal streamflows. The first half of winter looks promising, but much more snow is needed in the second half.

\* 90%, 70%, 30%, and 10% chances of exceeding are the probabilities that the actual flow will exceed the volumes in the table.

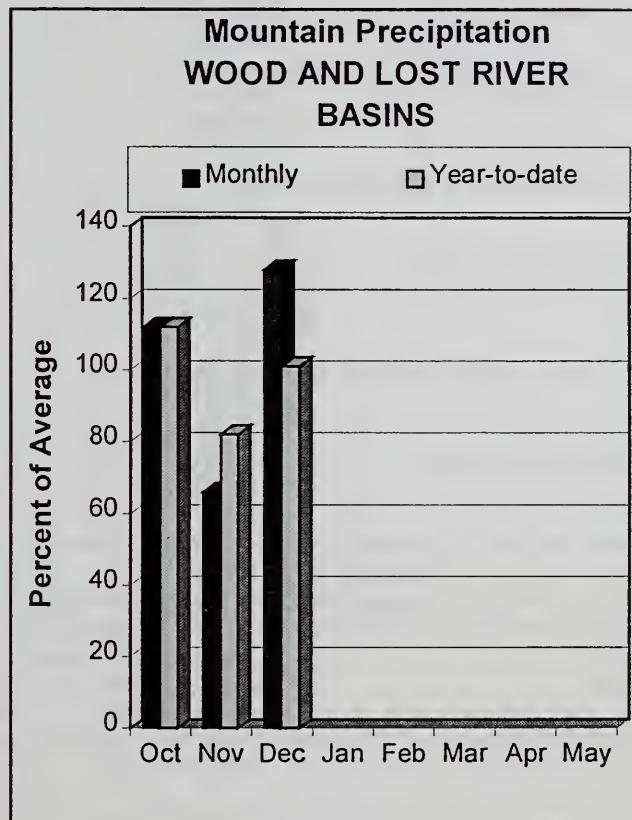

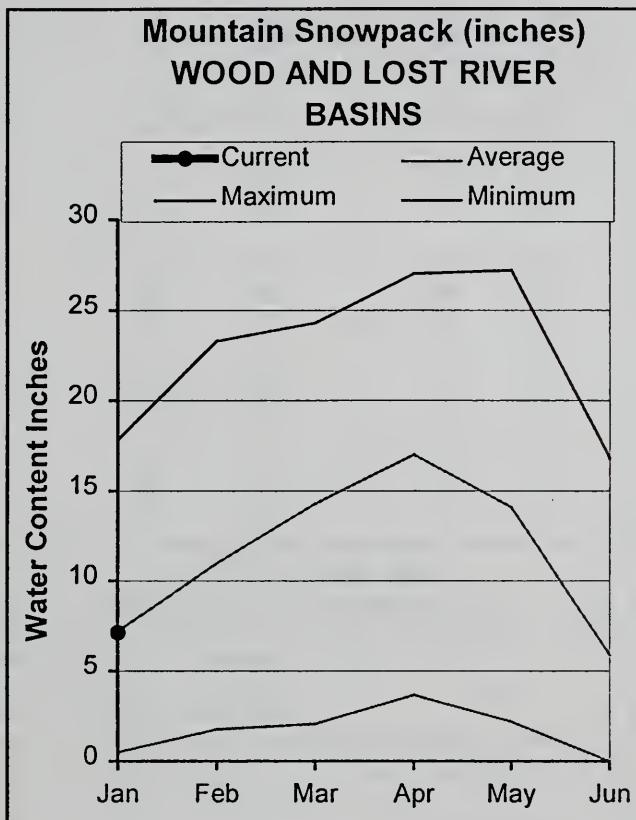

The average is computed for the 1971-2000 base period.

(1) - The values listed under the 10% and 90% Chance of Exceeding are actually 5% and 95% exceedance levels.

(2) - The value is natural flow - actual flow may be affected by upstream water management.

# WOOD and LOST RIVER BASINS

## JANUARY 1, 2002

## WATER SUPPLY OUTLOOK

The new water year started with above normal precipitation, 112% in October followed by November with only 66%, the lowest in the state. December brought 128% of average precipitation. Water year to date is normal. Low elevation snowpacks are off to a great start with Camas Creek at 169% of average. However, the higher elevation snowpacks, which are the most important, are only normal in the Big Wood and Little Wood basins. The snowpack decreases to 93% of average in the Big Lost and only 77% in the Birch-Medicine Lodge basins. Reservoir storage remains low and ranges from 7% full in Magic Reservoir to 34% full for Mackay Reservoir. Streamflow forecasts range from 80-100% of average. Much more snow is needed to satisfy the numerous water needs in these basins. Let's hope Mother Nature gets back on track and delivers more snow to these central Idaho Mountains.

# UPPER SNAKE RIVER BASIN

## JANUARY 1, 2002

## WATER SUPPLY OUTLOOK

Some of the season's first fall precipitation events fell as snow in the high country in the upper Snake basin. This means part of this winter's snowpack will be absorbed directly into the ground to recharge the soil profile. October precipitation was 118% of average, November was 83% and December brought 112%. Precipitation for the water year is normal at 102% of average. Snowpacks are the greatest in the low elevation drainages of Blackfoot, Willow, and Portneuf basins ranging from 106-115% of average, respectively. The lowest snowpacks are in the Teton, Snake above Jackson Lake, and Salt basins at 82% of average. Overall, the Snake basin above Palisades Reservoir is 86% of average, Henrys Fork is 91% and the Snake above American Falls reservoir is 92%. The 8 major reservoirs in the upper Snake basin are one-third full or half of normal. Jackson Lake is the lowest at 16% of capacity and Palisades Reservoir is only 31% full. Streamflow forecasts call for 75-90% of average. The season can still improve with more than half the winter still to come, but stay tuned we'll be watching these basins closely.

# SOUTHSIDE SNAKE RIVER BASINS

## JANUARY 1, 2002

## WATER SUPPLY OUTLOOK

The new water year started off slow in these southern Idaho basins with October precipitation at just 67% of average. November was better at 124% of average. December precipitation was like an early Christmas present with amounts ranging 110-190% of average. Snowpacks also shot up like a good day on the stock market with the Oakley basin snowpack reporting over 200% of average in mid-December. With the lack of moisture the last week of December, snowpack percentages dropped 20-30 percentage points. On January 1, snowpacks ranged from 145% of average in the Salmon Falls and Bruneau basins to 160% of average in the Oakley and Owyhee basins. Much more snow is needed, because even the Oakley basin has only two-thirds of its April 1 seasonal peak. These southern Idaho reservoirs are nearly empty. Salmon Falls Reservoir is the lowest in the state at 5% of capacity, 19% of average--the lowest December 31 storage reading since 1962. Oakley Reservoir is 13% full, 38% of average; Owyhee Reservoir is 15% full, 26% of average. Streamflow forecasts range from 95-115% of average in these high desert streams. With more than half the season still to come, let's hope the snow doesn't stop here and keeps falling the rest of the winter season.

# BEAR RIVER BASIN

## JANUARY 1, 2002

## WATER SUPPLY OUTLOOK

December brought above normal precipitation to the Bear River basin and also increased the water year to date precipitation to just above normal. Snow water content levels are near normal in most of these basins ranging from 95-115% of average. Some low elevation snow measuring stations, such as Oxford Spring SNOTEL at 6,740 feet in the Malad basin, has 7.3 inches of snow water; average is 4.9 inches. Last year at this time this site had 4.0 inches of snow water. Reservoir storage remains low with Bear Lake at 40% of capacity, 63% of average. Montpelier Creek Reservoir is 20% of capacity, which is about half of normal. Streamflow forecasts reflect the dry conditions from last year and call for only 85% of average. The water supply outlook can still improve with more than half the season still to come.

\* 90%, 70%, 30%, and 10% chances of exceeding are the probabilities that the actual flow will exceed the volumes in the table.

The average is computed for the 1971-2000 base period.

(1) - The values listed under the 10% and 90% Chance of Exceeding are actually 5% and 95% exceedance levels.  
 (2) - The value is natural flow - actual flow may be affected by upstream water management.

**Streamflow Adjustment List For All Forecasts Published In Idaho Basin Outlook Report** Streamflow forecasts are projections of runoff volumes that would have occurred naturally without influences from upstream reservoirs or diversions. These values are referred to as natural or adjusted flows. To make these adjustments, changes in reservoir storage, diversions, and inter-basin transfers are added or subtracted from the observed (actual) streamflow volumes. The following list documents the adjustments made to each forecast point in this report. (Revised 12/2000).

RESERVOIR CAPACITY DEFINITIONS (Units in 1,000 acre-feet, KAF)  
Different agencies use various definitions when reporting reservoir capacity and contents.  
Reservoir storage terms include dead, inactive, active, and surcharge storage. This table lists these volumes for each reservoir, and defines the storage volumes NRCS uses when reporting capacity and current reservoir storage. In most cases, NRCS reports usable storage, which includes active and inactive storage. (Revised January 2002)

<u>BASIN/RESERVOIR</u>	<u>DEAD STORAGE</u>	<u>INACTIVE STORAGE</u>	<u>SURCHARGE</u>	<u>NRCS CAPACITY</u>	<u>NRCS CAPACITY INCLUDES</u>
<u>PANHANDLE REGION</u>

## Interpreting Streamflow Forecasts

having too much water available during the forecast period, users can base their operational decisions on one of the forecasts with a smaller chance of being exceeded. These include:

**30 Percent Chance of Exceeding Forecast.** There is a 30 percent chance that the streamflow volume will exceed this forecast value. There is a 70 percent chance the streamflow volume will be less than this forecast value.

**10 Percent Chance of Exceeding Forecast.** there is a 10 percent chance that the streamflow volume will exceed this forecast value. There is a 90 percent chance the streamflow volume will be less than this forecast value.

**Most Probable (50 Percent Chance of Exceeding ) Forecast.** This forecast is the best estimate of streamflow volume that can be produced given current conditions and based on the outcome of similar past situations. There is a 50 percent chance that the streamflow volume will exceed this forecast value. There is a 50 percent chance that the streamflow volume will be less than this forecast value.

The most probable forecast will rarely be exactly right, due to errors resulting from future weather conditions and the forecast equation itself. This does not mean that users should not use the most probable forecast; it means that they need to evaluate existing circumstances and determine the amount of risk they are willing to take by accepting this forecast value.

### To Decrease the Chance of Having Too Little Water

If users want to make sure there is enough water available for their operations, they might determine that a 50 percent chance of the streamflow volume being lower than the most probable forecast is too much risk to take. To reduce the risk of not having enough water available during the forecast period, users can base their operational decisions on one of the forecasts with a greater chance of being exceeded (or possibly some point in-Between). These include:

**70 Percent Chance of Exceeding Forecast.** There is a 70 percent chance that the streamflow volume will exceed this forecast value.

There is a 30 percent chance the streamflow volume will be less than this forecast value.

**90 Percent Chance of Exceeding Forecast.** There is a 90 percent chance that the streamflow volume will exceed this forecast value.

There is a 10 percent chance the streamflow volume will be less than this forecast value.

### To Decrease the Chance of Having Too Much Water

If users want to make sure they don't have too much water, they might determine that a 50 percent chance of the streamflow being higher than the most probable forecast is too much of a risk to take. To reduce the risk of

### Using the forecasts - an example

**Using the Most Probable Forecast.** Using the example forecasts shown below, users can reasonably expect 36,000 acre-feet to flow past the gaging station on the Mary's River near Death between March 1 and July 31.

**Using the Higher Exceedence Forecasts.** If users anticipate a somewhat drier trend in the future (monthly and seasonal weather outlooks are available from the National Weather Service every two weeks), or if they are operating at a level where an unexpected shortage of water could cause problems, they might want to plan on receiving only 20,000 acre-feet (from the 70 percent chance of exceeding forecast). In seven out of ten years with similar conditions, streamflow volumes will exceed the 20,000 acre-foot forecast.

If users anticipate extremely dry conditions for the remainder of the season, or if they determine the risk of using the 70 percent chance of exceeding forecast is too great, then they might plan on receiving only 5000 acre-feet (from the 90 percent chance of exceeding forecast). Nine out of ten years with similar conditions, streamflow volumes will exceed the 5000 acre-foot forecast.

**Using the Lower Exceedance Forecasts.** If users expect wetter future conditions, or if the chance that five out of every ten years with similar conditions would produce streamflow volumes greater than 36,000 acre-feet was more than they would like to risk, they might plan on receiving 52,000 acre-feet (from the 30 percent chance of exceeding forecast) to minimize potential flooding problems. Three Out of ten years with similar conditions, streamflows will exceed the 52,000 acre-foot forecast.

In years when users expect extremely wet conditions for the remainder of the season and the threat of severe flooding and downstream damage exists, they might choose to use the 76,000 acre-foot (10 percent chance of exceeding) forecast for their water management operations. Streamflow volumes will exceed this level only one year out of ten.

### WEISER, PAYETTE, BOISE RIVER BASINS Streamflow Forecasts

Forecast Point	Forecast Period	<--> Drier	=> Future Conditions	=> Wetter	=>>
SF PAYETTE RIVER at Lowman	APR-JUL APR-SEP	329 369	414 459	471 521	109 107
